Status: Research and proposal, submitted to my manager and director. Not implemented.

Situation & Problem

As Supervisor, Onsite IT & Automation Systems, I identified a significant gap in our ServiceNow intake experience. The current-state workflow relied heavily on:

- vague, unstructured user submissions
- technicians requesting device information manually
- repeated back-and-forth clarification
- misrouted tickets and unnecessary delays

This created confusion and frustration for users and inefficiency for IT. More importantly, it prevented the organization from taking advantage of modern AI-driven capabilities offered in the ServiceNow platform, which would require additional licensing.

The absence of a structured, guided, and context-aware intake process meant:

- high volumes of low-value tickets
- inconsistent routing
- slower MTTR
- limited automation potential
- no scalable foundation for AI-assisted service delivery

The organization needed a modern intake model that could intercept misrouted requests, guide users to the correct workflows, and automatically capture the context technicians need to resolve issues quickly.

Objective

I developed an AI-Enhanced IT Intake & UX Modernization Roadmap, proposing a transition from a manual, technician-dependent intake model to a scalable, AI-optimized service experience. I submitted this research and proposal to my manager and director. The proposal was intended to build the case for adopting these capabilities, which would require additional licensing.

The roadmap aimed to:

- target a 25 – 40% reduction in low-value tickets (assumed range)
- improve MTTR through automatic device detection

- guide users to the correct catalog workflows
- leverage ServiceNow's Virtual Agent and Predictive Intelligence
- establish a foundation for AI-driven routing and deflection
- modernize the user experience across the Americas region

What I Proposed (The Roadmap)

a. AI-Optimized Intake Experience

The roadmap introduced a future-state intake model designed so that:

- AI detects user intent immediately
- device information is auto-populated
- the correct catalog workflow is shown without guesswork
- routing is accurate on the first attempt

This was designed to address the pain points of the current experience directly.

b. Virtual Agent–Driven Guided Workflows

Leveraging ServiceNow's Virtual Agent capabilities, the proposal recommended:

- keyword detection
- guided dialogs
- catalog redirection
- conversational intake

This would reduce friction and reduce the need for users to understand technical categories.

c. Predictive Intelligence for Routing

The roadmap incorporated Predictive Intelligence to:

- classify requests
- automate assignment
- reduce misrouting
- improve consistency across regions

This aligned with ServiceNow's native AI-driven routing engine.

d. Automatic Device Detection

To reduce technician follow-up, the roadmap included device lookup via:

- SCCM
- Intune
- Discovery

This would automatically attach device CI data to tickets, improving triage speed and accuracy.

e. Adaptive Forms & Dynamic Intake

The proposal recommended adaptive forms that:

- show or hide fields based on detected issue
- ensure required data is captured up front
- reduce noise and incomplete submissions

This would create a more intelligent, context-aware intake experience.

f. Proactive Notifications

The roadmap included proactive notifications for:

- known outages
- service events
- common SaaS disruptions

This would deflect unnecessary tickets and improve user experience.

g. 12-Month Phased Modernization Plan

The roadmap was structured into three phases:

0–3 Months (Quick Wins)

- AI intercept for Copilot/SaaS requests
- prevent mis-submitted Service Desk tickets
- device auto-capture at intake

3–6 Months (AI Scaling)

- Predictive Intelligence routing
- adaptive forms rollout
- proactive notifications

6–12 Months (Full Modernization)

- AI ticket deflection automation
- process mining for continual improvement
- expanded workflow automation

The phased approach was designed to deliver value incrementally while building toward fully AI-optimized intake.

Projected Impact (Modeled Outcomes)

The roadmap included a quantified ROI model. The inputs are illustrative assumptions, not measured data: a 10,000-ticket annual baseline, 30% deflection, $12 per ticket, and 0.5 hr MTTR improvement. These are projections, not measured results:

- **30%** AI deflection → an estimated 3,000 avoided tickets a year
- $12/ticket labor cost → an estimated **$36,000** in labor savings
- 0.5 hr MTTR improvement × 7,000 remaining tickets → an estimated **3,500** hours returned
- productivity uplift through faster resolution and fewer delays

These modeled outcomes were intended to support the business case for modernizing intake and adopting AI-aligned workflows.

Architectural Principles Applied

- AI-assisted intent detection
- device-context enrichment
- predictive routing
- guided, human-friendly UX
- automation-ready intake patterns

- proactive service communication
- phased modernization strategy
- alignment with ServiceNow's native AI capabilities

Summary

The IT Intake Modernization Roadmap (AI-Enhanced) was a strategic roadmap proposal designed to modernize the organization's ServiceNow intake experience. By combining AI-driven intent detection, automatic device capture, predictive routing, adaptive forms, and proactive notifications, the roadmap outlined a clear path toward a more efficient, scalable, and user-friendly IT service model.

This proposal outlined how the organization could reduce low-value tickets, improve MTTR, and establish a foundation for AI-driven service delivery, all through capabilities native to the ServiceNow platform, subject to additional licensing.
